Adobe PostScript

## Introduction

---

At first glance, JavaServer Pages™ (JSP) and Microsoft Active Server Pages (ASP) technologies have many similarities. Both are designed to create interactive pages as part of a Web-based application. To a degree, both enable developers to separate programming logic from page design through the use of components that are called from the page itself. And both provide an alternative to creating CGI scripts that makes page development and deployment easier and faster.

While JavaServer Pages technology and Microsoft Active Server Pages are similar in many ways, there are also a number of differences that exist. And these differences are just as significant as the similarities, and have far-reaching implications for the developers who use them as well as the organizations that adopt them as part of their overall Web-based architecture.

## JSP Technology: An Open Approach

---

In many ways, the biggest difference between JSP and ASP technologies lies in the approach to the software design itself. JSP technology is designed to be both platform and server independent, created with input from a broader community of tool, server, and database vendors. In contrast, ASP is a Microsoft technology that relies primarily on Microsoft technologies.

### Platform and Server Independence

JSP technology adheres to the Write Once, Run Anywhere™ philosophy of the Java™ architecture. Instead of being tied to a single platform or vendor, JSP technology can run on any Web server and is supported by a wide variety of tools from multiple vendors.

Because it uses ActiveX controls for its components, ASP technology is basically restricted to Microsoft Windows-based platforms. Offered primarily as a feature of Microsoft IIS, ASP technology does not work easily on a broader range of Web servers because ActiveX objects are platform specific.

Although ASP technology is available on other platforms through third-party porting products, to access components and interact with other services, the ActiveX objects must be present on the selected platform. If not present, a bridge to a platform supporting them is required.

## Open Development Process, Open Source

Sun developed JSP technology using the Java Community Process. Since 1995, Sun has used this open process to develop and revise Java technology and specifications in cooperation with the international Java community. Working with Sun in the JSP effort are authoring tool vendors (such as Macromedia), container companies (such as Apache and Netscape), end users, consultants, and others. Going forward, Sun is licensing the latest versions of JSP and Java™ Servlet (JSP 1.1 and Java Servlet 2.2) source code to Apache to be developed and released under the Apache development process. Apache, Sun, and a number of other companies and individuals will openly develop a robust reference implementation (RI) that is freely available to any company or individual. Additional information can be found at <http://jakarta.apache.org>.

The JSP application programming interface (API) has undoubtedly benefited — and will continue to benefit — from the input of this extended community. In contrast, ASP technology is a specifically Microsoft initiative, developed in a proprietary process.

	ASP Technology	JSP Technology
<b>Web Server</b>	Microsoft IIS or Personal Web Server	Any Web server, including Apache, Netscape, and IIS
<b>Platforms</b>	Microsoft Windows <sup>1</sup>	Most popular platforms, including the Solaris™ Operating Environment, Microsoft Windows, Mac OS, Linux, and other UNIX® platform implementations

1. Accessing other platforms requires third-party ASP porting products.

For a company selecting the components of a growing, Web-based information architecture, JSP technology provides a flexible, open choice that works with a wide variety of vendors' tools and reflects industry input and collaboration.

## The Developer's Perspective

---

Both ASP and JSP technologies let developers separate content generation from layout by accessing components from the page. ASP supports the COM model, while JSP technology provides components based on JavaBeans™ technology or JSP tags.

As noted previously, the differences outweigh the similarities.

### Extensible JSP Tags

The first difference apparent to any page author are the JSP tags themselves. While both ASP and JSP use a combination of tags and scripting to create dynamic Web pages, JSP technology enables developers to extend the JSP tags available. JSP developers can create custom tag libraries, so page authors can access more functionality using XML-like tags and depend less on scripting. With custom tags, developers can shield page authors from the complexities of page creation logic and extend key functions to a broader range of authors.

### Reusability Across Platforms

Developers will also notice the focus on reusability. The JSP components (Enterprise JavaBeans™, JavaBeans, or custom JSP tags) are reusable across platforms. An Enterprise JavaBean component accessing legacy databases can serve distributed systems on both UNIX and Microsoft Windows platforms. And the tag extension capability of JSP technology gives developers an easy, XML-like interface for sharing packaged functionality with page designers throughout the enterprise.

This component-based model speeds application development because it enables developers to:

- Build quick prototype applications using lightweight subcomponents, then integrate additional functionality as it becomes available
- Leverage work done elsewhere in the organization and encapsulate it in a JavaBean or Enterprise JavaBean component

## The Java Advantage

JSP technology uses the Java language for scripting, while ASP pages use Microsoft VBScript or JScript. The Java language is a mature, powerful, and scalable programming language that provides many benefits over the Basic-based scripting languages. For example, the Java language provides superior performance to the interpreted VBScript or JScript languages. Because they use Java technology and are compiled into Java servlets, JSP pages provide a gateway to the entire suite of server-side Java libraries for HTTP-aware applications.

The Java language makes the developer's job easier in other ways as well. For example, it helps protect against system crashes, while ASP applications on Windows NT systems are susceptible to crashing. The Java language also helps in the area of memory management by providing protection against memory leaks and hard-to-find pointer bugs that can slow application deployment. Plus, JSP provides the robust exception handling necessary for real-world applications.

## Easier Maintenance

Applications using JSP technology are easier to maintain over time than ASP-based applications.

- Scripting languages are fine for small applications, but do not scale well to manage large, complex applications. Because the Java language is structured, it is easier to build and maintain large, modular applications with it.
- JSP technology's emphasis on components over scripting makes it easier to revise content without affecting logic, or revise logic without changing content.

- The Enterprise JavaBeans architecture encapsulates the enterprise logic, such as database access, security, and transaction integrity, and isolates it from the application itself.
- Because JSP technology is an open, cross-platform architecture, Web servers, platforms, and other components can be easily upgraded or switched without affecting JSP-based applications. This makes JSP suitable for real-world Web applications, where constant change and growth is the norm.

	ASP Technology	JSP Technology
<b>Reusable, Cross-Platform Components</b>	No	JavaBeans, Enterprise JavaBeans, custom JSP tags
<b>Security Against System Crashes</b>	No	Yes
<b>Memory Leak Protection</b>	No	Yes
<b>Scripting Language</b>	VBScript, JScript	Java
<b>Customizable Tags</b>	No	Yes

## Scalability in the Enterprise

The Java 2 Platform, Enterprise Edition (J2EE) is the Java architecture for developing multitier enterprise applications. As part of J2EE, JSP pages have access to all J2EE components, including JavaBeans and Enterprise JavaBeans components and Java servlets. JSP pages are actually compiled into servlets, so they have all of the benefits of these flexible, server-side Java applications. The J2EE platform containers manage the complexities of enterprise applications, including transaction management and resource pooling.

JSP pages have access to all of the standard J2EE services, including:

- Java Naming and Directory Interface™ API
- JDBC™ API (communicating with relational databases)
- JavaMail™ (classes supporting Java-based mail and messaging applications)
- Java™ Message Service (JMS)

Through J2EE, JSP pages can interact with enterprise systems in many ways. J2EE supports two CORBA-compliant technologies: Java IDL and RMI-IIOP. With Enterprise JavaBeans technology, JSP pages can access databases using high-level, object-relational mappings.

Finally, because JSP technology was developed through the Java Community Process, it has wide support from tool, Web server and application server vendors. This enables users and partners take a best-of-breed approach, selecting the best tools for their specific applications while protecting their investment in code and in personnel training.

	ASP Technology	JSP Technology
Compatible with Legacy Databases	Yes (COM)	Yes (using JDBC API)

	ASP Technology	JSP Technology
<b>Ability to Integrate with Data Sources</b>	Works with any ODBC-compliant database	Works with any ODBC- and JDBC technology-compliant database
<b>Components</b>	COM components	JavaBeans, Enterprise JavaBeans, or extensible JSP tags
<b>Extensive Tool Support</b>	Yes	Yes
